Acute Low Back Problems in Adults: Assessment and Treatment
Attention Clinicians:

The Clinical Practice Guideline on which this Quick Reference Guide for Clinicians is based was developed by a multidisciplinary, private-sector panel comprising health care professionals and a consumer representative sponsored by the Agency for Health Care Policy and Research (AHCPR). Panel members were:

Stanley J. Bigos, MD (Chair)  
Reverend O. Richard Bowyer  
G. Richard Braen, MD  
Kathleen C. Brown, PhD, RN  
Richard A. Deyo, MD, MPH  
Scott Haldeman, MD, PhD, DC  
John L. Hart, DO  
Ernest W. Johnson, MD  
Robert B. Keller, MD  
Daniel K. Kido, MD  
Matthew H. Liang, MD, MPH  
Roger M. Nelson, PhD, PTT

Margareta Nordin, Dr. Med. Sc.  
Bernice D. Owen, PhD, RN  
Malcolm H. Pope, Dr. Med. Sc., PhD  
Richard K. Schwartz, MS, OTR  
Donald H. Stewart, Jr., MD  
Jeffrey L. Susman, MD  
John J. Triano, DC, MA  
Lucius Tripp, MD, MPH  
Dennis Turk, PhD  
Clark Watts, MD, JD  
James Weinstein, DO

Special consultants to the panel were: Michele Battie, PT, PhD; Claire Bombardier, MD; Nortin Hadler, MD; Alf Nachemson, MD, PhD; Gordon Waddell, MD. John Holland, MD, MPH and John Webster, MD served as project directors. Project methodologists were David Schriger, MD, MPH and Paul Shekelle, MD, MPH.

An explicit, science-based methodology was employed along with expert clinical judgment to develop specific statements on patient assessment and management on acute low back problems. Extensive literature searches were conducted and critical reviews and syntheses were used to evaluate empirical evidence and significant outcomes. Peer review and pilot testing were undertaken to evaluate the validity, reliability, and utility of the guideline in clinical practice.

This Quick Reference Guide for Clinicians presents a clinical strategy for applying the statements and recommendations from the Clinical Practice Guideline. The latter provides a description of the guideline development process, thorough analysis and discussion of the available research, critical evaluation of the assumptions and knowledge of the field, more complete information for health care decisionmaking, consideration for patients with special needs, and references. Decisions to adopt particular recommendations from either publication must be made by practitioners in light of available resources and circumstances presented by the individual patient.

AHCPR invites comments and suggestions from users for consideration in development and updating of future guidelines.

Abstract

This *Quick Reference Guide for Clinicians* contains highlights from the *Clinical Practice Guideline* version of *Acute Low Back Problems in Adults*, which was developed by a private-sector panel of health care providers and consumers. The *Quick Reference Guide* is an example of how a clinician might implement the panel’s findings and recommendations on the management of acute low back problems in working-age adults. Topics covered include the initial assessment of patients presenting with acute low back problems, identification of red flags that may indicate the presence of a serious underlying medical condition, initial management, special studies and diagnostic considerations, and further management considerations. Instructions for clinical testing for sciatic tension, recommendations for sitting and unassisted lifting, tests for identification of clinical pathology, and algorithms for patient management are included.

This document is in the public domain and may be used and reprinted without special permission. AHCPR appreciates citation as to source and the suggested format is provided below:

Purpose and Scope

Low back problems affect virtually everyone at some time during their life. Surveys indicate a yearly prevalence of symptoms in 50 percent of working age adults; 15-20 percent seek medical care. Low back problems rank high among the reasons for physician office visits and are costly in terms of medical treatment, lost productivity, and nonmonetary costs such as diminished ability to perform or enjoy usual activities. In fact, for persons under age 45, low back problems are the most common cause of disability.

Acute low back problems are defined as activity intolerance due to lower back or back-related leg symptoms of less than 3 months' duration. About 90 percent of patients with acute low back problems spontaneously recover activity tolerance within 1 month. The approach to a new episode in a patient with a recurrent low back problem is similar to that of a new acute episode.

The findings and recommendations included in the Clinical Practice Guideline define a paradigm shift away from focusing care exclusively on the pain and toward helping patients improve activity tolerance. The intent of this Quick Reference Guide is to bring to life this paradigm shift. The guide provides information on the detection of serious conditions that occasionally cause low back symptoms (conditions such as spinal fracture, tumor, infection, cauda equina syndrome, or non-spinal conditions). However, treatment of these conditions is beyond the scope of this guideline. In addition, the guideline does not address the care of patients younger than 18 years or those with chronic back problems (back-related activity limitations of greater than 3 months' duration).

Initial Assessment

- Seek potentially dangerous underlying conditions.
- In the absence of signs of dangerous conditions, there is no need for special studies since 90 percent of patients will recover spontaneously within 4 weeks.

A focused medical history and physical examination are sufficient to assess the patient with an acute or recurrent limitation due to low back symptoms of less than 4 weeks duration. Patient responses and findings on the history and physical examination, referred to as "red flags" (Table 1), raise suspicion of serious underlying spinal conditions. Their absence rules out the need for special studies during the first 4 weeks of symptoms when spontaneous recovery is expected. The medical history and physical examination can also alert the clinician to non-spinal pathology (abdominal, pelvic, thoracic) that
can present as low back symptoms. Acute low back symptoms can then be classified into one of three working categories:

- **Potentially serious spinal condition**—tumor, infection, spinal fracture, or a major neurologic compromise, such as cauda equina syndrome, suggested by a red flag.
- **Sciatica**—back-related lower limb symptoms suggesting lumbosacral nerve root compromise.
- **Nonspecific back symptoms**—occurring primarily in the back and suggesting neither nerve root compromise nor a serious underlying condition.

Medical History

In addition to detecting serious conditions and categorizing back symptoms, the medical history establishes rapport between the clinician and patient. The patient's description of present symptoms and limitations, duration of symptoms, and history of previous episodes defines the problem. It also provides insight into concerns, expectations, and nonphysical (psychological and socioeconomic) issues that may alter the patient's response to treatment. Assessment tools such as pain drawings and visual analog pain-rating scales may help further document the patient's perceptions and progress.

A patient's estimate of personal activity intolerance due to low back symptoms contributes to the clinical assessment of the severity of the back problem, guides treatment, and establishes a baseline for recommending daily activities and evaluating progress.

Open-ended questions, such as those listed below, can gauge the need for further discussion or specific inquiries for more detailed information:

- **What are your symptoms?**
  - Pain, numbness, weakness, stiffness?
  - Located primarily in back, leg, or both?
  - Constant or intermittent?

- **How do these symptoms limit you?**
  - How long can you sit, stand, walk?
  - How much weight can you lift?

- **When did the current limitations begin?**
  - How long have your activities been limited? More than 4 weeks?
  - Have you had similar episodes previously?
  - Previous testing or treatment?

- **What do you hope we can accomplish during this visit?**

Physical Examination

Guided by the medical history, the physical examination includes:

- General observation of the patient.
- A regional back exam.
- Neurologic screening.
- Testing for sciatic nerve root tension.

The examination is mostly subjective since patient response or interpretation is required for all parts except reflex testing and circumferential measurements for atrophy.
Addressing Red Flags

Physical examination evidence of severe neurologic compromise that correlates with the medical history may indicate a need for immediate consultation. The examination may further modify suspicions of tumor, infection, or significant trauma. A medical history suggestive of non-spinal pathology mimicking a back problem may warrant examination of pulses, abdomen, pelvis, or other areas.

Observation and Regional Back Examination

Limping or coordination problems indicate the need for specific neurologic testing. Severe guarding of lumbar motion in all planes may support a suspected diagnosis of spinal infection, tumor, or fracture. However, given marked variations among persons with and without symptoms, range-of-motion measurements of the back are of limited value.

Vertebral point tenderness to palpation, when associated with other signs or symptoms, may be suggestive of but not specific for spinal fracture or infection. Palpable soft-tissue tenderness is, by itself, an even less specific or reliable finding.

Neurologic Screening

The neurologic examination can focus on a few tests that seek evidence of nerve root impairment, peripheral neuropathy, or spinal cord dysfunction. Over 90 percent of all clinically significant lower extremity radiculopathy due to disc herniation involves the L5 or S1 nerve root at the L4-5 or L5-S1 disc level. The clinical features of nerve root compression are summarized in Figure 1.

Testing for Muscle Strength.
The patient's inability to toe walk (calf muscles, mostly S1 nerve root), heel walk (ankle and toe dorsiflexor muscles, L5 and some L4 nerve roots), or do a single squat and rise (quadriceps muscles, mostly L4 nerve root) may indicate muscle weakness. Specific testing of the dorsiflexor muscles of the ankle or great toe (suggestive of L5 or some L4 nerve root dysfunction), hamstrings and ankle evertors (L5-S1), and toe flexors (S1) is also important.

Circumferential Measurements. Muscle atrophy can be detected by circumferential measurements of the calf and thigh bilaterally. Differences of less than 2 cm in measurements of the two limbs at the same level may be a normal variation. Symmetrical muscle bulk and strength are expected unless the patient has a neurologic impairment or a history of lower extremity muscle or joint problem.

Reflexes. The ankle jerk reflex tests mostly the S1 nerve root and the knee jerk reflex tests mostly the L4 nerve root; neither tests the L5 nerve root. The reliability of reflex testing can be diminished in the presence of adjacent joint or muscle problems. Up-going toes in response to stroking the plantar footpad (Babinski or plantar
response) may indicate upper motor-neuron abnormalities (such as myelopathy or demyelinating disease) rather than a common low back problem.

**Sensory Examination.** Testing light touch or pressure in the medial (L4), dorsal (L5), and lateral (S1) aspects of the foot (Figure 1) is usually sufficient for sensory screening.

</table>
Clinical tests for sciatic tension

The straight leg raising (SLR) test (Figure 2) can detect tension on the L5 and/or S1 nerve root. SLR may reproduce leg pain by stretching nerve roots irritated by a disc herniation.

Figure 2. Instructions for the Straight Leg Raising (SLR) Test

1. Ask the patient to lie as straight as possible on a table in the supine position.

2. With one hand placed above the knee of the leg being examined, exert enough firm pressure to keep the knee fully extended. Ask the patient to relax.

3. With the other hand cupped under the heel, slowly raise the straight limb. Tell the patient, "If this bothers you, let me know, and I will stop."

4. Monitor for any movement of the pelvis before complaints are elicited. True sciatic tension should elicit complaints before the hamstrings are stretched enough to move the pelvis.

5. Estimate the degree of leg elevation that elicits complaint from the patient. Then determine the most distal area of discomfort: back, hip, thigh, knee, or below the knee.

6. While holding the leg at the limit of straight leg raising, dorsiflex the ankle. Note whether this aggravates the pain. Internal rotation of the limb can also increase the tension on the sciatic nerve roots.
Pain below the knee at less than 70 degrees of straight leg raising, aggravated by dorsiflexion of the ankle and relieved by ankle plantar flexion or external limb rotation, is most suggestive of tension on the L5 or S1 nerve root related to disc herniation. Reproducing back pain alone with SLR testing does not indicate significant nerve root tension.

**Crossover pain** occurs when straight raising of the patient’s well limb elicits pain in the leg with sciatica. Crossover pain is a stronger indication of nerve root compression than pain elicited from raising the straight painful limb.

**Sitting knee extension** (Figure 3) can also test sciatic tension. The patient with significant nerve root irritation tends to complain or lean backward to reduce tension on the nerve.

---

**Figure 3. Instructions for sitting knee extension test.**

With the patient sitting on a table, both hip and knees flexed at 90 degrees, slowly extend the knee as if evaluating the patella or bottom of the foot. This maneuver stretches nerve roots as much as a moderate degree of supine SLR.
Inconsistent Findings and Pain Behavior

The patient who embellishes a medical history, exaggerates pain drawings, or provides responses on physical examination inconsistent with known physiology can be particularly challenging. A strongly positive supine straight leg raising test without complaint on sitting knee extension and inconsistent responses on examination raise a suspicion that nonphysical factors may be affecting the patient’s responses. “Pain behaviors” (verbal or nonverbal communication of distress or suffering) such as amplified grimacing, distorted gait or posture, moaning, and rubbing of painful body parts may also cloud medical issues and even evoke angry responses from the clinician.

Interpreting inconsistencies or pain behaviors as malingering does not benefit the patient or the clinician. It is more useful to view such behavior and inconsistencies as the patient’s attempt to enlist the practitioner as an advocate, a plea for help. The patient could be trapped in a job where activity requirements are unrealistic relative to the person’s age or health. In some cases, the patient may be negotiating with an insurer or be involved in legal actions. In patients with recurrent back problems, inconsistencies and amplifications may simply be habits learned during previous medical evaluations. In working with these patients, the clinician should attempt to identify any psychological or socioeconomic pressures that might be influenced in a positive manner. The overall goal should always be to facilitate the patient’s recovery and avoid the development of chronic low back disability.
Algorithm 1.
Initial evaluation of acute low back problem

Adults with < 3 months of activity intolerance due to low back pain and/or back-related leg symptoms.

Perform focused medical history and physical examination.
Search for "RED FLAGS" (Table 1).
Examination includes neurologic screening and straight leg raising test (SLR).

Yes

Any RED FLAGS?

RED FLAGS for spine fracture.
Plain x-ray of lumbosacral spine.
If after 10 days, fracture still suspected, or multiple sites of pain, consider bone scan and consultation before defining anatomy with CT.

RED FLAGS for cancer/ infection.
CBC, ESR, U/A
If still suspicious, consider consultation or seek further evidence with bone scan, x-ray, or other lab.
Negative x-ray alone does not rule out disease.
If positive, define anatomy with MRI.

RED FLAGS for cauda equina syndrome or rapidly progressing neurologic deficit.
Immediate consultation for emergency studies and definitive care.

No

In the absence of RED FLAGS, diagnostic testing is not clinically helpful in first 4 weeks of symptoms.

Evidence of serious disease?

Yes

Arrange appropriate treatment or consultation.

No

Evidence of non-spinal medical problems causing referred back complaints?

Yes

Go to Algorithm 2

No

Exit Algorithm
Initial Care

- Education and assurance.
- Patient comfort.
- Activity alterations.

Patient Education

If the initial assessment detects no serious condition, assure the patient that there is “no hint of a dangerous problem” and that “a rapid recovery can be expected.” The need for education will vary among patients and during various stages of care. An obviously apprehensive patient may require a more detailed explanation. Patients with sciatica may have a longer expected recovery time than patients with nonspecific back symptoms and thus may need more education and reassurance. Any patient who does not recover within a few weeks may need more extensive education about back problems and the reassurance that special studies may be considered if recovery is slow.

Patient Comfort

Comfort is often a patient’s first concern. Nonprescription analgesics will provide sufficient pain relief for most patients with acute low back symptoms. If treatment response is inadequate, as evidenced by continued symptoms and activity limitations, prescribed pharmaceuticals or physical methods may be added. Comorbid conditions, side effects, cost, and provider/patient preference should guide the clinician’s choice of recommendations. Table 2 summarizes comfort options.

Oral Pharmaceuticals

The safest effective medication for acute low back problems appears to be acetaminophen. Nonsteroidal anti-inflammatory drugs (NSAIDs), including aspirin and ibuprofen, are also effective although they can cause gastrointestinal irritation/ulceration or (less commonly) renal or allergic problems. Phenylbutazone is not recommended due to risks of bone marrow suppression. Acetaminophen may be used safely in combination with NSAIDs or other pharmacologic or physical therapeutics, especially in otherwise healthy patients.

Muscle relaxants seem no more effective than NSAIDs for treating patients with low back symptoms, and using them in combination with NSAIDs has no demonstrated benefit. Side effects including drowsiness have been reported in up to 30 percent of patients taking muscle relaxants.

Opioids appear no more effective than safer analgesics for managing low back symptoms. Opioids should be avoided if possible and, when chosen, used only for a short time. Poor patient tolerance and risks of drowsiness, decreased reaction time, clouded judgment, and potential misuse/dependence have been reported in up to 35 percent of patients. Patients should be warned of these potentially debilitating problems.

¹Aspirin and other NSAIDs are not recommended for use in combination with one another due to the risk of GI complications.
²Equivocal efficacy.
³Significant potential for producing drowsiness and debilitation; potential for dependency.
⁴Short course (few days only) for severe symptoms.
Physical Methods

- **Manipulation**, defined as manual loading of the spine using short or long leverage methods, is safe and effective for patients in the first month of acute low back symptoms without radiculopathy. For patients with symptoms lasting longer than 1 month, manipulation is probably safe but its efficacy is unproven. If manipulation has not resulted in symptomatic and functional improvement after 4 weeks, it should be stopped and the patient reevaluated.

- **Traction** applied to the spine has not been found effective for treating acute low back symptoms.

- **Physical modalities** such as massage, diathermy, ultrasound, cutaneous laser treatment, biofeedback, and transcutaneous electrical nerve stimulation (TENS) also have no proven efficacy in the treatment of acute low back symptoms. If requested, the clinician may wish to provide the patient with instructions on self-application of heat or cold therapy for temporary symptom relief.

- **Invasive techniques** such as needle acupuncture and injection procedures (injection of trigger points in the back; injection of facet joints; injection of steroids, lidocaine, or opioids in the epidural space) have no proven benefit in the treatment of acute low back symptoms.

- **Other miscellaneous therapies** have been evaluated. No evidence indicates that shoe lifts are effective in treating acute low back symptoms or limitations, especially when the difference in lower limb length is less than 2 cm. Shoe insoles are a safe and inexpensive option if requested by patients with low back symptoms who must stand for prolonged periods. Low back corsets and back belts, however, do not appear beneficial for treating acute low back symptoms.
Activity Alteration

To avoid both undue back irritation and debilitation from inactivity, recommendations for alternate activity can be helpful. Most patients will not require bed rest. Prolonged bed rest (more than 4 days) has potential debilitating effects, and its efficacy in the treatment of acute low back problems is unproven. Two to four days of bed rest are reserved for patients with the most severe limitations (due primarily to leg pain).

Avoiding undue back irritation. Activities and postures that increase stress on the back also tend to aggravate back symptoms. Patients limited by back symptoms can minimize the stress of lifting by keeping any lifted object close to the body at the level of the navel. Twisting, bending, and reaching while lifting also increase stress on the back. Sitting, although safe, may aggravate symptoms for some patients. Advise these patients to avoid prolonged sitting and to change position often. A soft support placed at the small of the back, armrests to support some body weight, and a slight recline of the chair back may make required sitting more comfortable.

Avoiding debilitation. Until the patient returns to normal activity, aerobic (endurance) conditioning exercise such as walking, stationary biking, swimming, and even light jogging may be recommended to help avoid debilitation from inactivity. An incremental, gradually increasing regimen of aerobic exercise (up to 20 to 30 minutes daily) can usually be started within the first 2 weeks of symptoms. Such conditioning activities have been found to stress the back no more than sitting for an equal time period on the side of the bed. Patients should be informed that exercise may increase symptoms slightly at first. If intolerable, some exercise alteration is usually helpful.

Conditioning exercises for trunk muscles are more mechanically stressful to the back than aerobic exercise. Such exercises are not recommended during the first few weeks of symptoms, although they may later help patients regain and maintain activity tolerance.

There is no evidence to indicate that back-specific exercise machines are effective for treating acute low back problems. Neither is there evidence that stretching of the back helps patients with acute symptoms.
Work Activities

When requested, clinicians may choose to offer specific instructions about activity at work for patients with acute limitations due to low back symptoms. The patient’s age, general health, and perceptions of safe limits of sitting, standing, walking or lifting (noted on initial history) can help provide reasonable starting points for activity recommendations. Table 3 provides a guide for recommendations about sitting and lifting. The clinician should make clear to patients and employers that:

- Even moderately heavy unassisted lifting may aggravate back symptoms.
- Any restrictions are intended to allow for spontaneous recovery or time to build activity tolerance through exercise.

Activity restrictions are prescribed for a short time period only, depending upon work requirements (no benefits apparent beyond 3 months).

¹Without getting up and moving around.
²Modification of NIOSH Lifting Guidelines, 1981, 1993. Gradually increase unassisted lifting limits to 60 lbs (men) and 35 lbs (women) by 3 months even with continued symptoms. Instruct patient to limit twisting, bending, reaching while lifting and to hold lifted object as close to navel as possible.
Algorithm 2. Treatment of acute low back problem on initial and followup visits

Initial visit

Adults with low back problem and no underlying serious condition (see Algorithm 1).

Provide assurance; education about back problems.

Does patient require help relieving symptoms?

Yes

Recommend/prescribe comfort options based on risk/benefits and patient preference (Table 2).

No

Recommend activity alterations to avoid back irritation.
Review activity limitations (if any) due to back problem; encourage to continue or return to normal activities (including work, with or without restrictions) as soon as possible.
Encourage low-stress aerobic exercise.

Symptoms improving?

Yes

Return to Normal Activities

No

Followup visits

Change in symptoms?

Yes

Review history and physical findings

No

Symptom recurrence?

Yes

Return to Algorithm 1

No

Go to Algorithm 3

Has reasonable activity tolerance returned within 4 weeks?

Yes

Return to Normal Activities

No

Any RED FLAGS?

No

Support return to work or required daily activities.
Can begin muscle conditioning exercises after a few weeks.

Yes

Provide assurance that recovery is expected.
Recommend activities to avoid debilitation and reduce risk of recurrence.
Routine testing (laboratory tests, plain x-rays of the lumbosacral spine) and imaging studies are not recommended during the first month of activity limitation due to back symptoms except when a red flag noted on history or examination raises suspicion of a dangerous low back or non-spinal condition. If a patient's limitations due to low back symptoms do not improve in 4 weeks, reassessment is recommended. After again reviewing the patient's activity limitations, history, and physical findings, the clinician may then consider further diagnostic studies, and discuss these with the patient.

**Timing and Limits of Special Studies**

Waiting 4 weeks before considering special tests allows 90 percent of patients to recover spontaneously and avoids unneeded procedures. This also reduces the potential confusion of falsely labeling age-related changes on imaging studies (commonly noted in patients older than 30 without back symptoms) as the cause of the acute symptoms. In the absence of either red flags or persistent activity limitations due to continuous limb symptoms, imaging studies (especially plain x-rays) rarely provide information that changes the clinical approach to the acute low back problem.

**Selection of Special Studies**

Prior to ordering imaging studies the clinician should have noted either of the following:

- The emergence of a red flag.
- Physiologic evidence of tissue insult or neurologic dysfunction.

Physiologic evidence may be in the form of definitive nerve findings on physical examination, electrodiagnostic studies (when evaluating sciatica), and a laboratory test or bone scan (when evaluating nonspecific low back symptoms). Unquestionable findings that identify specific nerve root compromise on the neurologic examination (see Figure 1) are sufficient physiologic evidence to warrant imaging. When the neurologic examination is less clear, however, further physiologic evidence of nerve root dysfunction should be considered before ordering an imaging study. Electromyography (EMG) including H-reflex tests may be useful to identify subtle focal neurologic dysfunction in patients with leg symptoms lasting longer than 3-4 weeks. Sensory evoked potentials (SEPs) may be added to the assessment if spinal stenosis or spinal cord myelopathy is suspected.

Laboratory tests such as erythrocyte sedimentation rate (ESR), complete blood count (CBC), and urinalysis (UA) can be useful to screen for nonspecific medical diseases (especially infection and tumor) of the low back. A bone scan can detect physiologic reactions to suspected spinal tumor, infection, or occult fracture.

Should physiologic evidence indicate tissue insult or nerve impairment, discuss with a consultant selection of an imaging test to define
a potential anatomic cause (CT for bone, MRI for neural or other soft tissue). Anatomic definition is commonly needed to guide surgery or specific procedures. Selection of an imaging test should also take into consideration any patient allergies to contrast media (myelogram) or concerns about claustrophobia (MRI) and costs. A discussion with a specialist on selection of the most clinically valuable study can often assist the primary care clinician to avoid duplication. Table 4 provides a general comparison of the abilities of different techniques to identify physiologic insult and define anatomic defects. Missing from the table is discography, which is not recommended for assessing patients with acute low back symptoms.

In general, an imaging study may be an appropriate consideration for the patient whose limitations due to consistent symptoms have persisted for 1 month or more:

- When surgery is being considered for treatment of a specific detectable loss of neurologic function.
- To further evaluate potentially serious spinal pathology.

Reliance upon imaging studies alone to evaluate the source of low back symptoms, however, carries a significant risk of diagnostic confusion, given the possibility of falsely identifying a finding that was present before symptoms began.

Management Considerations After Special Studies

Definitive treatment for serious conditions (see Table 1) detected by special studies is beyond the scope of this guideline. When special studies fail to define the exact cause of symptoms, however, no patient should receive an impression that the clinician thinks “nothing is wrong” or that the problem could be “in their head.” Assure the patient that a clinical workup is highly successful in detecting serious conditions, but does not reveal the precise cause of most low back symptoms.

Surgical Considerations

Within the first 3 months of acute low back symptoms, surgery is considered only when serious spinal pathology or nerve root dysfunction obviously due to a herniated lumbar disc is detected. A disc herniation, characterized by protrusion of the central nucleus pulposus through a defect in the outer annulus fibrosis, may trap a nerve root causing irritation, leg symptoms and nerve root dysfunction. The presence of a herniated lumbar disc on an imaging study, however, does not necessarily imply nerve root dysfunction. Studies of asymptomatic adults commonly demonstrate intervertebral disc herniations that apparently do not entrap a nerve root or cause symptoms.

Therefore, nerve root decompression can be considered for a patient if all of the following criteria exist:

- Sciatica is both severe and disabling.
- Symptoms of sciatica persist without improvement for longer than 4 weeks or with extreme progression.
- There is strong physiologic evidence of dysfunction of a specific nerve root with intervertebral disc herniation confirmed at the corresponding level and side by findings on an imaging study.

Patients with acute low back pain alone, without findings of serious conditions or significant nerve root compression, rarely benefit from a surgical consultation. Many patients with strong clinical findings of nerve root dysfunction due to disc herniation recover activity tolerance within 1 month; no evidence indicates that delaying surgery for this period worsens outcomes. With or without an operation, more than 80 percent of patients with obvious surgical indications eventually recover. Surgery seems to be a luxury for speeding recovery of patients with obvious surgical indications but benefits fewer than 40 percent of patients with questionable physiologic findings. Moreover, surgery increases the chance of future procedures with higher complication rates. Overall, the incidence of first-time disc surgery complications, including infection and bleeding, is less than 1 percent. The figure increases dramatically with older patients or repeated procedures.
Direct and indirect nerve root decompression for herniated discs. Direct methods of nerve root decompression include laminotomy (expansion of the interlaminar space for access to the nerve root and the offending disc fragments), microdiscectomy (laminotomy using a microscope), and laminectomy (total removal of laminae). Methods of indirect nerve root decompression include chemonucleolysis, the injection of chymopapain or other enzymes to dissolve the inner disc. Such chemical treatment methods are less efficacious than standard or microdiscectomy and have rare but serious complications. Any of these methods is preferable to percutaneous discectomy (indirect, mechanical disc removal through a lateral disc puncture).

Management of spinal stenosis. Usually resulting from soft tissue and bony encroachment of the spinal canal and nerve roots, spinal stenosis typically has a gradual onset and begins in older adults. It is characterized by nonspecific limb symptoms, called neurogenic claudication or pseudoclaudication, that interfere with the duration of comfortable standing and walking. The symptoms are commonly bilateral and rarely associated with strong focal findings on examination.

Neurogenic claudication, however, can be confused or coexist with vascular claudication, in which leg pain also limits walking. The symptoms of vascular insufficiency can be relieved by simply standing still while relief of neurogenic claudication symptoms usually require the patient to flex the lumbar spine or sit.

The surgical treatment for spinal stenosis is usually complete laminectomy for posterior decompression. Offending soft tissue and osteophytes that encroach upon nerve roots in the central spinal canal and foramen are removed. Fusion may be considered to stabilize a degenerative spondylolisthesis with motion between the slipped vertebra and adjacent vertebrae. Elderly patients with spinal stenosis who tolerate their daily activities usually need no surgery unless they develop new signs of bowel or bladder dysfunction. Decisions on treatment should take into account the patient’s preference, lifestyle, other medical problems, and risks of surgery. Surgery for spinal stenosis is rarely considered in the first 3 months of symptoms. Except for cases of trauma-related spinal fracture or dislocation, fusion alone is not usually considered in the first 3 months following onset of low back symptoms.
Algorithm 4. Surgical considerations for patients with persistent sciatica

Adult limited by significant sciatica persisting > 4 weeks; specific problem defined by physiologic evidence and imaging study (see Algorithm 3).

Primary care clinician and/or surgeon reviews test results with patient and discusses surgery vs. other treatment. Consider both short- and long-term outcomes.

Will patient consider surgery to speed recovery?

Yes

Are physical limitations lessening?

Yes

Refer to surgeon for specific recommendations based on expected short- and long-term outcomes

Surgery performed?

Yes

Postsurgical care.

No

Go to Algorithm 5

No

Refer to surgeon for specific recommendations based on expected short- and long-term outcomes

Surgery performed?

Yes

Postsurgical care.

No

Following diagnostic or surgical procedures, the management of most patients becomes focused on improving physical conditioning through an incrementally increased exercise program. The goal of this program is to build activity tolerance and overcome individual limitations due to back symptoms. At this point in treatment, symptom control methods are only an adjunct to making prescribed exercises more tolerable.

- Begin with low-stress aerobic activities to improve general stamina (walking, riding a bicycle, swimming, and eventually jogging).

- Exercises to condition specific trunk muscles can be added a few weeks after. The back muscles may need to be in better condition than before the problem occurred. Otherwise, the back may continue to be painful and easily irritated by even mild activity. Following back surgery, recovery of activity tolerance may be delayed until protective muscles are conditioned well enough to compensate for any remaining structural changes.

- Finally, specific training to perform activities required at home or work can begin. The objective of this program is to increase the patient's tolerance in carrying out actual daily duties.

When patients demonstrate difficulty regaining the ability to tolerate the activities they are required (or would like) to do, the clinician may pose the following diagnostic and treatment questions:

- Could the patient have a serious, undetected medical condition? A careful review of the medical history and physical examination is warranted.

- Are the patient's activity goals realistic? Exploring briefly the patient's expectations, both short- and long-term, of being able to perform specific activities at home, work, or recreation may help the patient assess whether such activity levels are actually achievable.

- If for any reason the achievement of activity goals seems unlikely, what are the patient's remaining options? To answer this question, the patient is often required to gather specific information from family, friends, employers, or others. If, on followup visits, the patient has made no effort to gather such information, the clinician has the opportunity to point out that low back symptoms alone rarely prevent a patient from addressing questions so important to his or her future. This observation can lead to an open, nonjudgmental discussion of common but complicated psychosocial problems or other issues that often can interfere with a patient's recovery from low back problems. The clinician can then help the patient address or arrange further evaluation of any specific problem limiting the patient's progress. This can usually be accomplished as the patient continues, with the clinician's encouragement, to build activity tolerance through safe, simple exercises.
Algorithm 5. Further management of acute low back problem

Adults with back-related activity limitations of > 4 weeks, < 3 months duration following special studies or surgery (see Algorithms 3,4).

Return to Normal Activities

Assure patient. Establish safe exercise plan to build tolerance for intended activity.

Yes

Recovery?

Yes

Recommend comfort options (Table 2) considering risk/benefits related to exercise.

No

Does patient require help with comfort to tolerate increasing activity and exercise?

No

Yes

Is patient overcoming activity intolerance?

Yes

Return to Algorithm 3 or seek consultation.

No

Review history, physical findings, and results of special testing.

Further questions about diagnosis?

Yes

Is patient seeking information about options?

No

Help patient consider options.

Yes

Is patient convinced he/she will be able to tolerate intended activity?

Yes

Point out that back symptoms rarely prevent individuals from seeking information. Ask if other factors could be involved.

No

Address specific issues or arrange for psychosocial evaluation.

No

Continue to encourage daily exercise to maximize activity tolerance and reduce recurrence of low back problems.

Recovery?

Yes

Return to Normal Activities
Table 5. Summary of Guideline Recommendations

The ratings in parentheses indicate the scientific evidence supporting each recommenda-
tion according to the following scale:

A = strong research-based evidence (multiple relevant and high-quality scientific studies).
B = moderate research-based evidence (one relevant, high-quality scientific study or
multiple adequate scientific studies).
C = limited research-based evidence (at least one adequate scientific study in patients
with low back pain).
D = panel interpretation of evidence not meeting inclusion criteria for research-based
evidence.

The number of studies meeting panel review criteria is noted for each category.

Availability of Guidelines

For each clinical practice guideline developed under the sponsorship of the Agency for Health Care Policy and Research (AHCPR), several versions are produced to meet different needs.

The Clinical Practice Guideline presents recommendations for health care providers with brief supporting information, tables and figures, and pertinent references.

The Quick Reference Guide for Clinicians is a distilled version of the Clinical Practice Guideline, with summary points for ready reference on a day-to-day basis.

The Consumer Version, available in English and Spanish, is an information booklet for the general public to increase patient knowledge and involvement in health care decisionmaking.

To order single copies of guideline products or to obtain further information on their availability, call the AHCPR Publications Clearinghouse toll-free at 800-358-9295 or write to: AHCPR Publications Clearinghouse, P.O. Box 8547, Silver Spring, MD 20907.

Single copies of the Clinical Practice Guideline are available for sale from the Government Printing Office, Superintendent of Documents, Washington, DC 20402, with a 25-percent discount given for bulk orders of 100 copies or more. The Quick Reference Guide for Clinicians and the Consumer Version in English are also available for sale in bulk quantities only. Call (202) 512-1800 for price and ordering information.

The Guideline Technical Report contains complete supporting materials for the Clinical Practice Guideline, including background information, methodology, literature review, scientific evidence tables, recommendations for research, and a comprehensive bibliography. It is available from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22161. Call (703) 487-4650 for price and ordering information.

The full text of guideline documents for online retrieval may be accessed through a free, electronic service from the National Library of Medicine called HSTAT (Health Services/Technology Assessment Text). Guideline information is also available through some of the computer-based information systems of the National Technical Information Service, professional associations, nonprofit organizations, and commercial enterprises.

A fact sheet describing Online Access for Clinical Practice Guidelines (AHCPR Publication No. 94-0075) and copies of the Quick Reference Guide for Clinicians and the Consumer Version of each guideline are available through AHCPR’s InstantFAX, a fax-on-demand service that operates 24 hours a day, 7 days a week. AHCPR’s InstantFAX is accessible to anyone using a facsimile machine equipped with a touchtone telephone handset: Dial (301) 594-2800, push “1,” and then press the facsimile machine’s start button for instructions and a list of currently available publications.
